NanoFASE

All models need input parameters

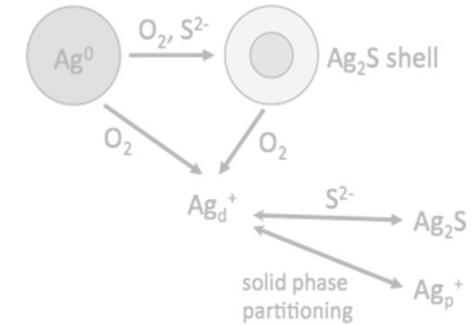

Liu & Cohen, ES&T 2014

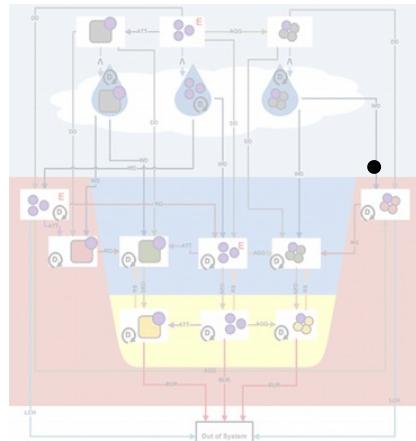

- Environmental parameters
 - water chemistry, hydrology
 - soil properties
 - meteorological data
 - ...
 - Nanoparticle characteristicsA map of the James River Basin in Virginia, overlaid with various environmental parameters and processes. Labels include: Inflow, Outflow, Dissolution, Reaction, Land use, Topography, Water quality, WWTP & runoff loads, Chemical deposition/scour, and a chemical reaction symbol. Arrows indicate the flow of water and the movement of particles or pollutants through the system.

Dale et al., ES&T 2015

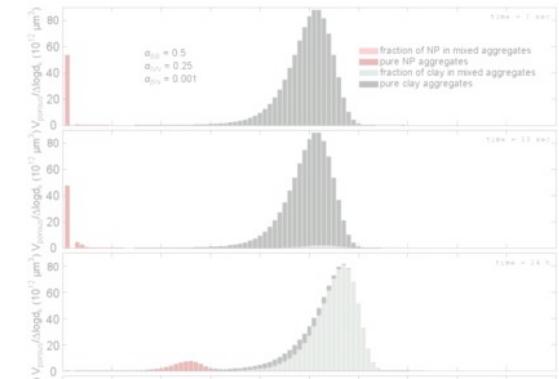

Dale et al., ES&T 2012

Meesters et al., ES&T 2014

- # Process descriptions

 - aggregation rate constants
 - attachment efficiencies
 - dissolution rate constants
 - surface transformation rate constants
 - ...

Theiszien et al., ES&T 2014

Purpose of models & experiments

Models can be:

Conceptual

Quantitative

Purpose of models & experiments

Models can be:

Conceptual

Experiments can:

Qualitatively inform models

Quantitative

Provide quantitative input parameters

Modelers: “there is not enough data”

Modelers: “there is not enough data”

→ *Is that really true after 10 years of
Nano EHS research?*

We have generated a lot of data in 10 years of Nano EHS research (and already before that)

→ *But a lot of this data cannot be used for modeling*

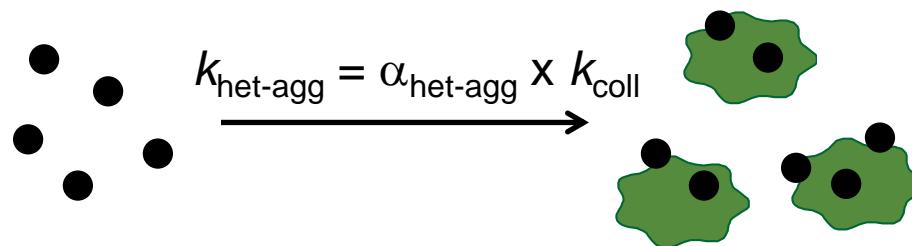

Issues/challenges

experiments

models

1. Data needs for models and experimental outputs do not always align

Example:
heteroaggregation

- **aggregation rate constants ($k_{\text{het-agg}}$)**
- **attachment efficiencies ($\alpha_{\text{het-agg}}$)**

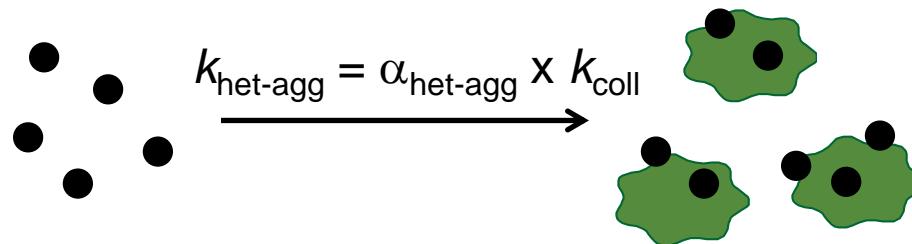

Issues/challenges

experiments

models

1. Data needs for models and experimental outputs do not always align

Example:
heteroaggregation

Experiment outputs

- % removal
- sedimentation rates
- aggregation curves
- distribution coefficients (K_d)*

- **aggregation rate constants ($k_{\text{het-agg}}$)**
- **attachment efficiencies ($\alpha_{\text{het-agg}}$)**

*for further information on why K_d is not valid for nanoparticles see:
Praetorius et al. ES Nano 2014

Issues/challenges

experiments

models

2. Limited application range of experimental method in terms of:

- a) environmental properties (e.g. method does not work at high IS, only without NOM)
- a) nanoparticles types (e.g. method only work for magnetic NPs)
- a) Measured parameter (e.g. many heteroaggregation experiments can resolve a values between 0.01 and 1, but might to assess values of 10^{-7})

Issues/challenges

experiments → models

3. Mismatched levels of accuracy

- a) Large scale models (e.g. regional/global fate & transport models)
→ favor wide range of parameter measurements over high accuracy

Issues/challenges

experiments → models

3. Mismatched levels of accuracy

- a) Large scale models (e.g. regional/global fate & transport models)
→ favor wide range of parameter measurements over high accuracy
- b) Small scale models (e.g. detailed aggregation model)
→ need for highly resolved measurements (e.g. property x for several NP sizes)

Issues/challenges

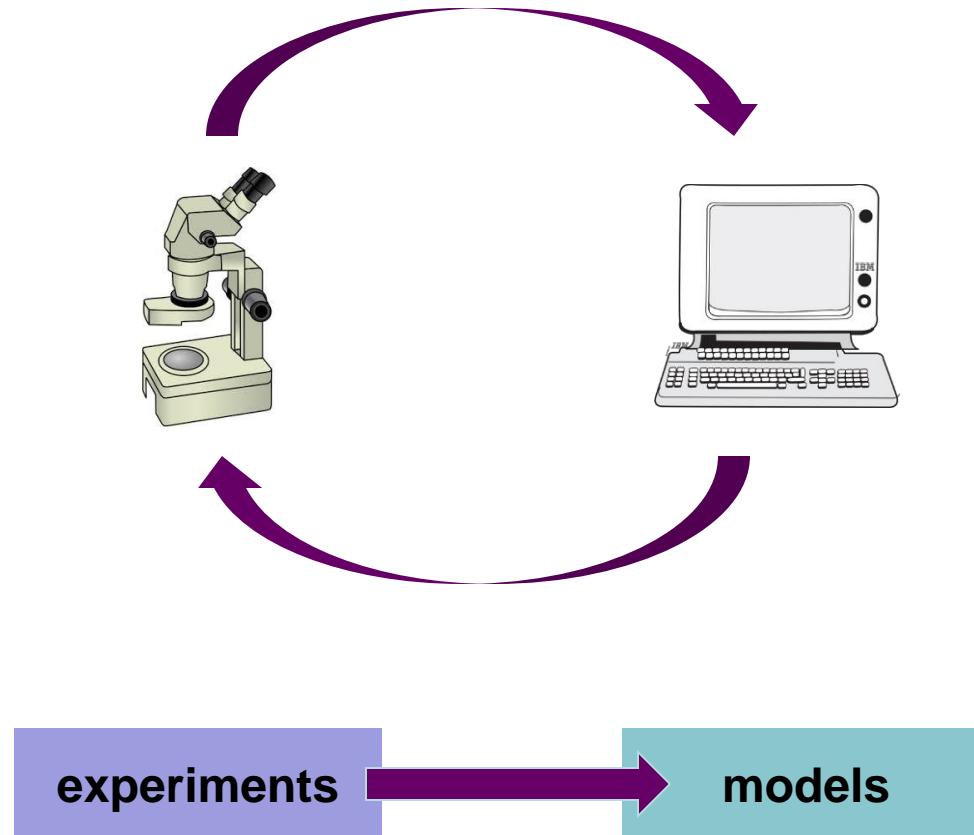

experiments → models

4. Insufficient understanding of measured data

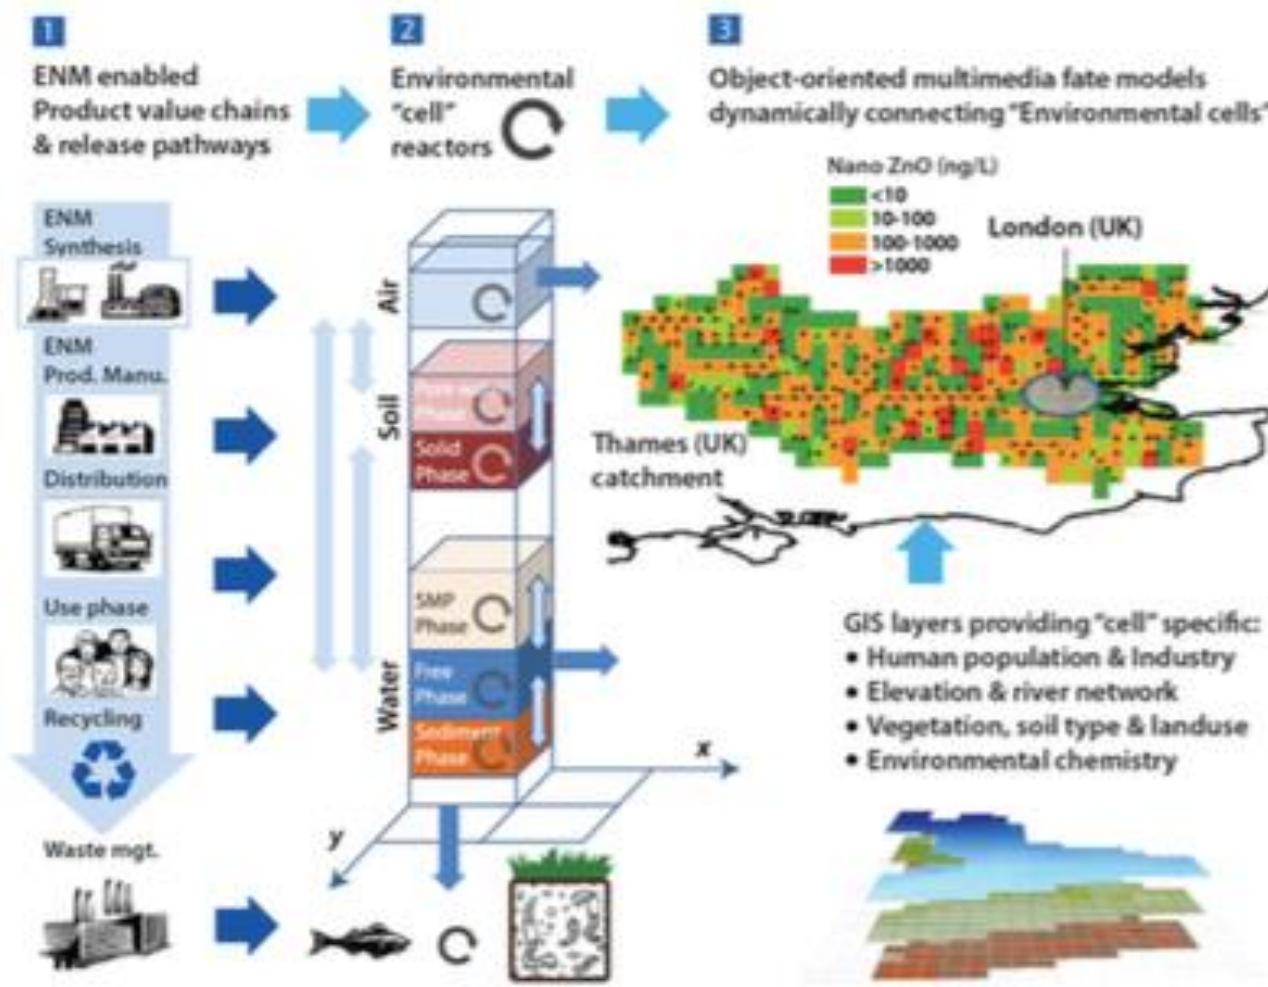

- a) How time consuming/costly is a measurement?
- a) How reliable is the method?
- a) What are common error sources?
- a) Can we quantify the uncertainty?
- b) What are the limits of the method?

→ We need to improve communication and direct collaboration between modelers and laboratory scientists!

NanoFASE project

Conclusions

experiments → models

1. We need to align experiment output with data needs of models
2. Choice of experimental method according to required application range and needs for accuracy
3. Need to increase communication between modelers and researchers in the lab
4. Make use of existing knowledge and qualitative results for first estimates before designing new methods
